New Diagram - Analytics BackEnd System Design

Web Analytics BackEnd System Design

Web/Mobile Visitor Tracking Code
Web pages gets tracked by the GA embed tracking code. It loads an async script that assigns a tracking cookie to
the user if it is not set. It also sends an XHR request for every user interaction.

Load Balancer
HAProxy, which stands for High Availability Proxy, is a popular open source software TCP/HTTP Load Balancer
and proxying solution. Its most common use is to improve the performance and reliability of a server
environment by distributing the workload across multiple servers.
A backend can contain one or many servers in it—generally speak multiple servers. It is a backend as contain one or many servers in it—generally speak multiple servers. Increases reliability is also
achieved through this manner, in case some of your backend servers become unavailable.
HAProxy routes the requests coming from Web Mobile Velors rise to the Zuul API Gateway of the solution.
Given the nature of a distributed system built for scalability and stateless request and response handling we
can distribute the Zuul API gateways spread across geographies. HAProxy performs load balancing (layer 4 +
proxy) across our Zuul nodes. High-Availability (HA) is provided via Keepalived.

API Gateway and service discovery:

Zuuli sa nAPI galaway and edge service that provise requests to multiple backing services. It provides a unline "flortd door" to the application occeystem, which allows any browser, mobile app or other user interface to consume services form multiple hosts. Zuuli s intergrated with other Nettis: tack components like Hybrits for fault tolerance and Eureks for service discovery or use it to manage routing rules, filters and bad balancing access your yetem. Most importantly all of those components are well adaptive by Spring farmenwich through An API gateway is a layer 7 (HTTP) router that acts as a reverse proxy for upstream services that reside inside your platform. API gateway are they ready configured to router traffic based on URII paths and have become expecially popular in the microservices world because exposing potentially hundreds of services to the Internet is both a security registrates and occess and scales a solid a security registrates and occess and scales a contract of the provided of the

Spring Boot Microservices
Using a microservices approach to application development can improve realience and expedite the time to market, but breaking apps into fine-grained services offers complications. With fine-grained services and lightweight protocols, microservices offers increased modularity, making applications easier to develop, settle dependent emportantly, change and maintain. With microservices, the code is troken into independent deploy, and, more importantly change and maintain. With microservices, the code is troken into independent. Scalability is the key aspect of microservices. Because each service is a separate component, we can scale up a single function or service without having to scale the entire application. Business-critical services can be deployed on multiple servers for increased availability and performance without impacting the performance of other system downtime, solve service and unappeteder responses. Here, lack stakening is important. When at failure arises, the troubled service should still run in a degraded functionality without crashing the entire system. Hyerix Circuit-treaker will come nitor secure in such failure sensitive. Here, lack stakening is important. When at failure arises, the troubled service should still run in a degraded functionality without crashing the entire system. Hyerix Circuit-treaker will come nitor secure in such failure sensitive. Here, in a such staken to the service of the complete state of the microservices are designed for scalability, resilience, fault-treates cluster. Distributed and segorgraphically spread Just Poll gradent gystem is designed for scalability, right availability, realience and fault-tolerance using distributed of treating Processing, the microservices will riggest data to Kalka Streams data

ishing and subscribing to streams of records ing streams of records in a fault-tolerant, durable way vides a unified, high-throughput, low-latiency, horizontally scalable platform that is used in production in

Storing streams or unified, high-throughput, low-latency, horzontary science year.

It provides a unified, high-throughput, low-latency, horzontary science years thousands of companies.

Kells of the provided of the provid

messaging system. Kafka is run as a cluster on one or more servers that can span multiple datacenters spread across geographies Those servers are usually called brokers.

Kafka uses Zookeeper to store metadata about brokers, topics and partitions. Kafka Streams is a pretty fast, lightweight stream processing solution that works best if all of the data ingestion is coming through Apache Kafika. The ingested data is read directly from Kaha by Apache Spark for stream processing and creates Timeseries Ignite RDD (Resilient Distributed Datasets).

Apache Spark
Spark Streaming is an extension of the core Spark API that enables scalable, high-throughput, fault-tolerant
stream processing of live data streams.
It provides a high-level abstraction called a discretized stream, or DStream, which represents a confinuous strea

of data.

Distreams can be created either from input data streams from sources such as Kafka, Flume, and Kinesis, or by applying high-level operations on other DStreams. Internally, a DStream is represented as a sequence of RDDs (Resilient) Distributed Datasets).

Apache Ignite
Apache Ignite is a distributed memory-centric database and caching platform that is used by Apache Spark users

o: Achieve true in-memory performance at scale and avoid data movement from a data source to Spark workers

With lighte, Spark users can configure primary and secondary indexes that can bring up to 1000x performance gains.

Cassandria is a lighty scalable and available distributed database that facilitates and allows storing and managing high velocity structured data across multiple commodity servers without a single point of failure. The Apache Cassandria is an interprise power for the primary powerful open source distributed database system that works extremely servers. It can be easily scaled to meet sudden increase in demand, by deploying multi-node Cassandria clusters, meets high availability requirements, and there is no single point of failure. Apache Cassandria has best write and read performance. Characteristics of Cassandria:

Highly consistent, fault-tolerant, and scalable

The data model is based on Google Bigliable
